Absolute Maximum Ratings

Stresses above the ratings listed below can cause permanent damage to the 9LPRS477D. These ratings, which are standard values for IDT commercially rated parts, are stress ratings only. Functional operation of the device at these or any other conditions above those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods can affect product reliability. Electrical parameters are guaranteed only over the recommended operating temperature range.

²Single-ended measurement at crossing point. Value is maximum – minimum over all time. DC value of common mode is not important due to the blocking cap.

³Minimum Frequency is a result of 0.5% down spread spectrum

⁴Differential measurement through the range of ±100 mV, differential signal must remain monotonic and within slew rate spec when crossing through this region.

⁵Defined as the total variation of all crossing voltages of CLK rising and CLK# falling. Matching applies to rising edge rate of CLK and falling edge of CLK#. It is measured using a +/-75mV window centered on the average cross point where CLK meets CLK#.

⁶Max difference of t_{CYCLE} between any two adjacent cycles.

⁷Accumulated tjc. over a 10μs time period, measured with JIT2 TIE at 50ps interval.

⁸ $V_D(PK-PK)$ is the overall magnitude of the differential signal.

⁹ $V_D(min)$ is the amplitude of the ring-back differential measurement, guaranteed by design, that ring-back will not cross 0V V_D . $V_D(max)$ is the largest amplitude allowed.

¹⁰The difference in magnitude of two adjacent V_D_DC measurements. V_D_DC is the stable post overshoot and ring-back part of the signal.
